

QUAKES-A: Quantifying Uncertainty and Kinematics of Earthquake Systems

Andrea Donnellan

Jet Propulsion Laboratory, California Institute of technology

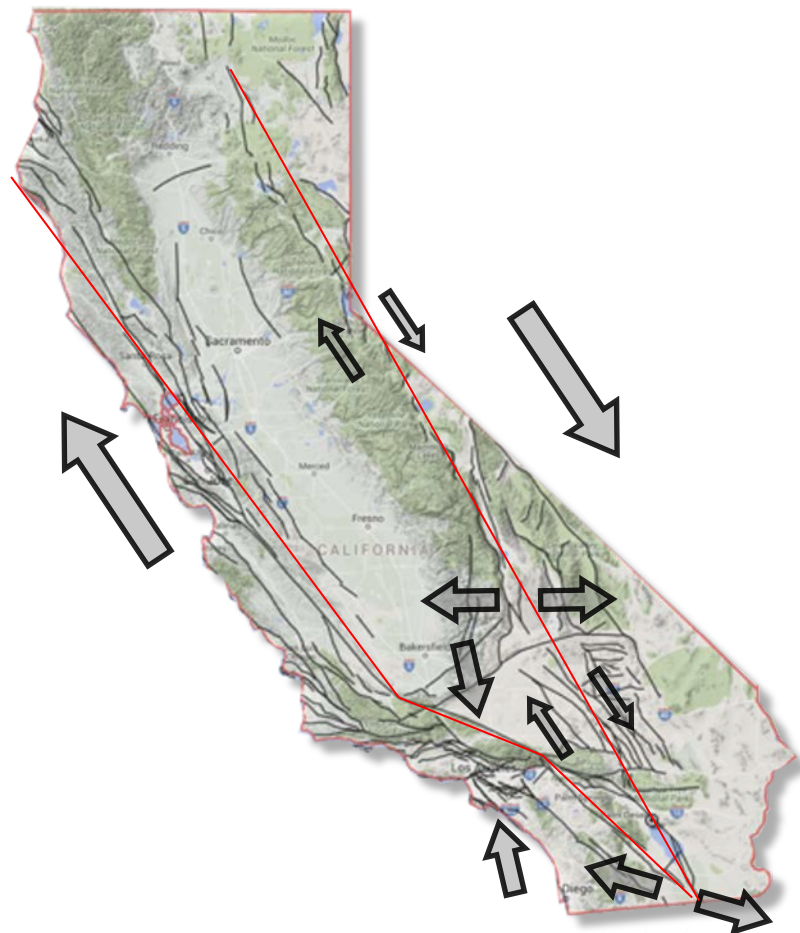

ESTF 2020

June 25, 2020

Create a uniform crustal deformation reference model for the active plate margin of California

- Fused InSAR, topographic, and GNSS geodetic imaging data
- Quantify uncertainties for the reference model
- Improve earthquake forecast models
- Improve understanding of the physical processes leading to and following earthquakes

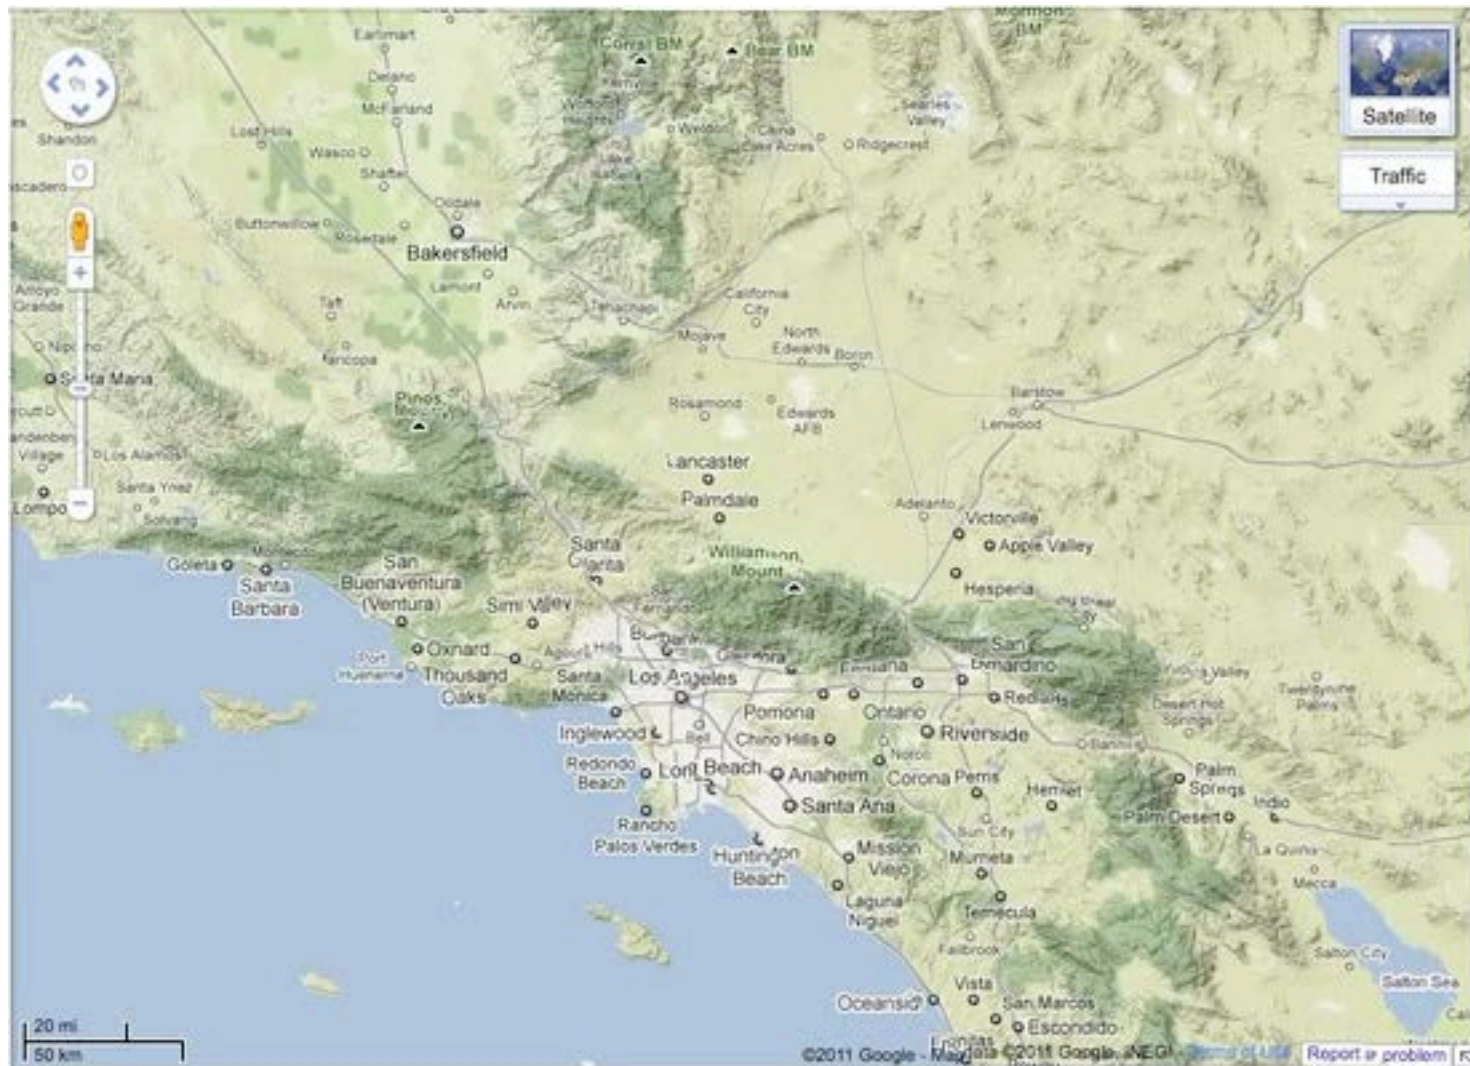

- Adjust UAVSAR processing with GNSS displacements and extract slip features
- Identify and rank active fault systems using GNSS cluster analysis
- Fuse and interpolate geodetic products to provide a uniformly sampled deformation field
- Assimilate and correlate the crustal deformation products into seismicity-based earthquake forecasts

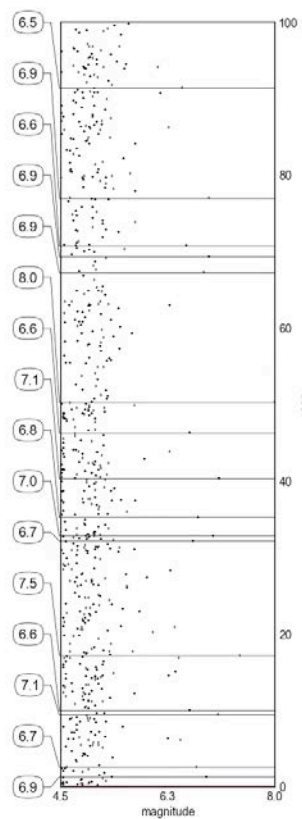

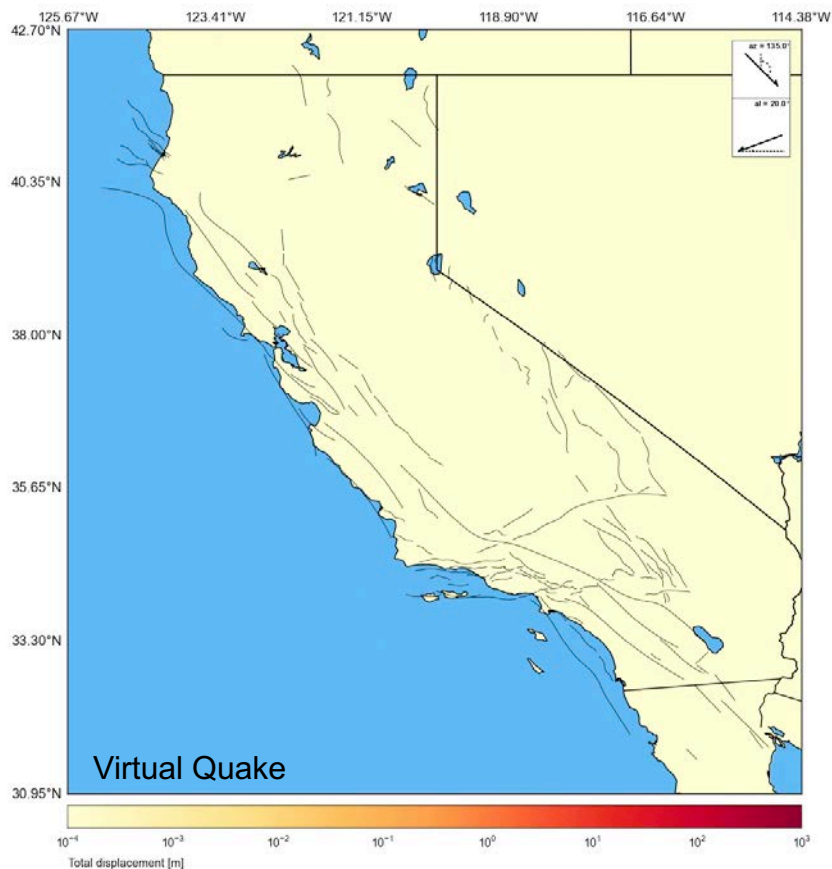

Conceptual View of Southern California Fault Motions

Crustal Deformation and Earthquakes are Non-Uniform in Space and Time

Motivates need for time-dependent gridded (uniform) crustal deformation model

Data Types/Products

GNSS

Network based
Deformation and Displacement

InSAR

Deformation and Displacement
Airborne: Configurable flight path
Spaceborne: Global systematic

Stereo Photogrammetry

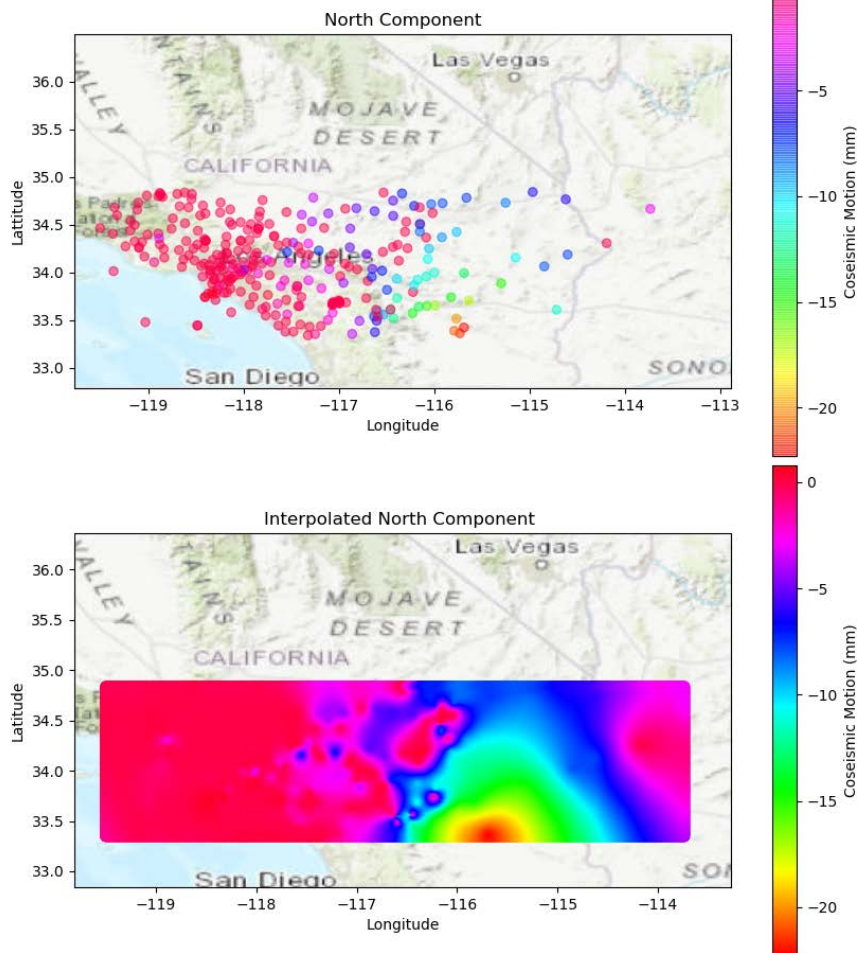

Topography and Change
Near Surface: targeted ultra high resolution
Airborne: configurable high resolution wide swath
Spaceborne: Global wide area

Lidar

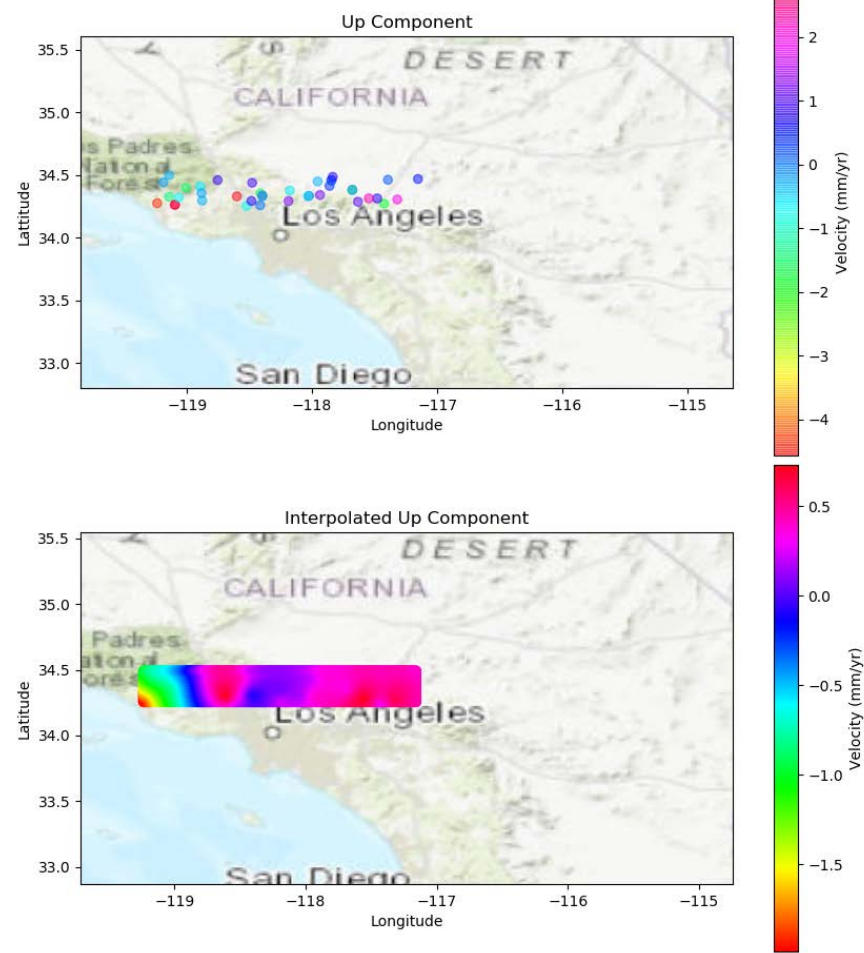

Topography and Change
Near-Surface: high resolution
Airborne: fault scale coverage
Spaceborne: Global systematic

Interpolation

Coseismic (north)

Velocity (vertical)

1. Creates synthetic interferogram for UAVSAR baseline adjustment
2. Creates initial uniform posting gridded deformation field

UAVSAR Baseline Adjustment

Enables extraction of plate tectonic motion and variations

Baseline Adjustment Highlights Fault Creep

- Fuse multiple geodetic methods to determine spatio-temporal variations in crustal deformation
- Construct a time-dependent uniformly gridded product
- Serves as reference for modeling and analysis
